

Qualys Container Security

Release Notes

Version 1.10.0.1

June 7, 2021

We addressed the following issues in Container Security 1.10.0.1.

Issues Addressed

- We fixed an issue where registry scan jobs were getting stuck in Queued/Running state. With this fix, we are marking scans as Failed when they cannot be recovered.
- We fixed a registry scanning issue where we were not returning updated image tag names in a repository when docker image tags were being added and removed in the repository. Now this issue is fixed.
- We fixed an issue where scans were being skipped and users saw an error message to Contact Qualys Support when some part of the image config had an invalid format. Now we skip the section that is not in the right format and continue with the image scan. In this case, some metadata information will be missing like docker layers information.
- We fixed an issue where the error “Internal server error” (http error code : 500) was returned for v1/containers endpoint. With this fix, we are now showing the correct data from the Qualys backend.
- We updated documentation for the collection of Kubernetes cluster attributes to explain that Kubernetes attributes will only be processed for containers discovered after the version 1.10 release.
